Thank you for sharing..In the prior art, the field of data storage is continually evolving to increase the amount of data that can be stored per unit volume. Typically, there is a tradeoff between the physical density of data storage media, e.g. the storage capacity per unit volume, and data reliability, e.g.

the amount of data loss or corruption that can be tolerated before a storage medium cannot be used reliably. For example, a spinning storage medium such as a disk may be able to store a larger amount of data than a solid-state storage medium such as a flash memory. However, the bit error rate of a spinning disk is typically larger than a solid-state storage medium such as a flash memory. Corruption of stored data can be caused by a number of factors. One factor is the data storage medium itself. For example, non-uniformity of a spinning storage medium can

cause localized damage to a stored bit. Another factor is the storage process. For example, a write-modify-read process that stores a pair of data bits (e
